

PAIRWISE EQUAL CHARGE SOLUTION IN KERR-SCHILD FORM

After failing to express the 2-charge pairwise equal charge solution in the ansatz structure from Wu, we attempt to express the pairwise equal charge solution in a Kerr-Schild-like form. That is, we attempt to express the metric in the form

$$ds^2 = d\bar{s}^2 + \frac{2m}{U}(k_\mu dx^\mu)^2 \quad (1)$$

where $d\bar{s}^2$ is a AdS_4 background metric we expect from the massless limit and the 1-form k_μ is linear to the electric gauge potentials.

The logic we follow in this section is quite straight forward – alike how Wu has sought the Cvetič-Youm solutions, I look at the $g = 0$ limit to obtain the appropriate coordinate transformation.

Proposition. Upon the following reparametrisation of the ungauged metric ($g = 0$) with charge

$$R^2 = (r + 2ms_1^2)(r + 2ms_2^2) \quad (2)$$

we arrive at the following form (the new coordinate R is simply written as r)

$$\begin{aligned} ds^2 = & -dt^2 + (r^2 + a^2 \cos^2 \theta) \left(\frac{dr^2}{\Delta_r} + d\theta^2 \right) + (a^2 + r^2) \sin^2 \theta d\phi^2 \\ & + \frac{2mU}{r^2 + a^2 \cos^2 \theta} (dt - a \sin^2 \theta d\phi)^2 \end{aligned} \quad (3)$$

with

$$\begin{aligned} \Delta_r = & (r^2 + m^2(s_1^2 - s_2^2)^2) \left[a^2 + r^2 - 2mU \right] / r^2 \\ U = & (1 + s_1^2 + s_2^2) \sqrt{r^2 + m^2(s_1^2 - s_2^2)^2} - m[s_1^2(1 + s_1^2) + s_2^2(1 + s_2^2)] \end{aligned} \quad (4)$$

The metric shows similarities with that of the ungauged, uncharged Wu form:

$$\begin{aligned} ds^2 = & -dt^2 + (r^2 + a^2 \cos^2 \theta) \left(\frac{dr^2}{r^2 + a^2 - 2mr} + d\theta^2 \right) + (a^2 + r^2) \sin^2 \theta d\phi^2 \\ & + \frac{2mr}{r^2 + a^2 \cos^2 \theta} (dt - a \sin^2 \theta d\phi)^2 \end{aligned} \quad (5)$$

Proposition. In the case of the gauged case ($g \neq 0$), the result is similar. Upon the same

reparametrisation, we arrive at

$$\begin{aligned}
ds^2 = & - \frac{(1 + g^2 r^2)(1 - a^2 g^2 \cos^2 \theta)}{1 - a^2 g^2} dt^2 \\
& + (r^2 + a^2 \cos^2 \theta) \left(\frac{dr^2}{\Delta_r} + \frac{d\theta^2}{1 - a^2 g^2 \cos^2 \theta} \right) \\
& + \frac{r^2 + a^2}{1 - a^2 g^2} \sin^2 \theta d\phi^2 + \frac{2mU}{r^2 + a^2 \cos^2 \theta} \left(\frac{1 - a^2 g^2 \cos^2 \theta}{1 - a^2 g^2} dt - \frac{a}{1 - a^2 g^2} \sin^2 \theta d\phi \right)^2
\end{aligned} \tag{6}$$

with

$$\Delta_r = (r^2 + m^2(s_1^2 - s_2^2)^2) \left[(r^2 + a^2)(1 + g^2 r^2) - 2mU \right] / r^2 \tag{7}$$

and the same U defined above. This again shows a resemblance to the gauged but uncharged solution:

$$\begin{aligned}
ds^2 = & - \frac{(1 + g^2 r^2)(1 - a^2 g^2 \cos^2 \theta)}{1 - a^2 g^2} dt^2 \\
& + (r^2 + a^2 \cos^2 \theta) \left(\frac{dr^2}{(r^2 + a^2)(1 + g^2 r^2) - 2mr} + \frac{d\theta^2}{1 - a^2 g^2 \cos^2 \theta} \right) \\
& + \frac{r^2 + a^2}{1 - a^2 g^2} \sin^2 \theta d\phi^2 + \frac{2mr}{r^2 + a^2 \cos^2 \theta} \left(\frac{1 - a^2 g^2 \cos^2 \theta}{1 - a^2 g^2} dt - \frac{a}{1 - a^2 g^2} \sin^2 \theta d\phi \right)^2
\end{aligned} \tag{8}$$

CONVENTION MATCHING

With the two independent charge solution perfectly fitting into the Wu form, we now attempt to fit the four charge ungauged case into the Wu form. For this to be properly set up, we first need to match conventions. Using the duality transformation

$$\begin{cases} F^2 = e^{-\varphi_1 + \varphi_2 - \varphi_3} \star (\tilde{\mathcal{F}}_2 + \chi_3 e^{2\varphi_3} \mathcal{F}^1) - \chi_1 (\tilde{\mathcal{F}}_3 + \chi_3 F^4) \\ F^3 = e^{-\varphi_1 - \varphi_2 + \varphi_3} \star (\tilde{\mathcal{F}}_3 + \chi_2 e^{2\varphi_2} \mathcal{F}^1) - \chi_1 (\tilde{\mathcal{F}}_2 + \chi_2 F^4) \end{cases}$$

COEFFICIENT DETERMINATION ALGORITHM

At the current stage of the project, there is a need for the determining the coefficients of the gauge-linear terms. In this section, I suggest that the method of achieving this is by performing a Taylor series expansion in terms of the charges. Here, we consider the following examples (all of which were proven to be in the Wu form). Ultimately, we will want to apply this logic to the four charge ungauged solution.

- (i) Three charge AdS₅ solution
- (ii) Two charge AdS₄ solution

Example. (Two charge AdS₄) We first present the explicit form of the solution and the gauge fields.

$$ds^2 = (H_1 H_2)^{1/2} \left[-dt^2 + \Sigma \left(\frac{dr^2}{r^2 + a^2 - 2mr} + d\theta^2 \right) + (r^2 + a^2) \sin^2 \theta d\phi^2 \right. \\ \left. + \frac{s_1^2}{(s_1^2 - s_2^2)} \left(\frac{1}{1 - 1/H_1} \right) A_1^2 + \frac{s_2^2}{(s_2^2 - s_1^2)} \left(\frac{1}{1 - 1/H_2} \right) A_2^2 \right]$$

Meanwhile, the gauge fields are given as

$$A_i = \left(1 - \frac{1}{H_i} \right) \left(\frac{c_i}{s_i} dt - \frac{c_1 c_2}{s_i c_i} a \sin^2 \theta d\phi \right)$$

where

$$H_i = 1 + \frac{2mr s_i^2}{\Sigma} \quad c_i = \sqrt{1 + s_i^2}$$

Performing a Taylor expansion of the terms inside the warp factor with respect to s_2 we find (up to $O(s_2^4)$ terms and subtracting the pure AdS terms)

$$\begin{cases} O(0) : & \frac{1}{s_1^2} \left(1 - \frac{1}{H_1} \right) (c_1 dt - c_2 a \sin^2 \theta d\phi)^2 \\ O(s_2^2) : & \frac{1}{s_1^4} \left(1 - \frac{1}{H_1} \right) (c_1 dt - c_2 a \sin^2 \theta d\phi)^2 - \frac{2mr}{\Sigma s_1^2} (c_2 dt - c_1 a \sin^2 \theta d\phi)^2 \end{cases}$$

Doing the same for s_1 ,

$$\begin{cases} O(0) : & \frac{1}{s_2^2} \left(1 - \frac{1}{H_2} \right) (c_2 dt - c_1 a \sin^2 \theta d\phi)^2 \\ O(s_1^2) : & \frac{1}{s_2^4} \left(1 - \frac{1}{H_2} \right) (c_2 dt - c_1 a \sin^2 \theta d\phi)^2 - \frac{2mr}{\Sigma s_2^2} (c_1 dt - c_2 a \sin^2 \theta d\phi)^2 \end{cases}$$

Example. (Three charge AdS₅ solution) We first present the explicit form of the solution and the gauge fields.

$$ds^2 = (H_1 H_2 H_3)^{1/3} \left[-dt^2 + \Sigma \left(\frac{r^2 dr^2}{(r^2 + a^2)(r^2 + b^2) - 2mr} + d\theta^2 \right) + (r^2 + a^2) \sin^2 \theta d\phi^2 \right. \\ \left. + (r^2 + b^2) \cos^2 \theta d\psi^2 + \frac{s_1^2}{(s_1^2 - s_2^2)(s_1^2 - s_3^2)} \left(\frac{\Sigma H_1}{2m} \right) A_1^2 \right. \\ \left. + \frac{s_2^2}{(s_2^2 - s_1^2)(s_2^2 - s_3^2)} \left(\frac{\Sigma H_2}{2m} \right) A_2^2 + \frac{s_3}{(s_3^2 - s_1^2)(s_3^2 - s_2^2)} \left(\frac{\Sigma H_3}{2m} \right) A_3^2 \right]$$

Meanwhile, the gauge fields are given as

$$A_i = \frac{2m}{\Sigma H_i} \left[\frac{s_i c_1 c_2 c_3}{c_i} \left(\frac{c_i^2}{c_1 c_2 c_3} dt - a \sin^2 \theta d\phi - b \cos^2 \theta d\psi \right) + \frac{c_i s_1 s_2 s_3}{s_i} \left(b \sin^2 \theta d\phi + a \cos^2 \theta d\psi \right) \right]$$

where

$$H_i = 1 + \frac{2ms_i^2}{\Sigma} \quad c_i = \sqrt{1 + s_i^2}$$

Performing a Taylor expansion of the terms inside the warp factor with respect to (s_2, s_3) we find (up to $O(s_2^4, s_3^4)$ terms and subtracting the pure AdS terms)

$$O(0) : \frac{2m}{\Sigma} \left[\frac{1}{H_1} \frac{1}{s_1^2} \left(c_1 dt - \frac{c_1 c_2 c_3}{c_1} (a \sin^2 \theta d\phi + b \cos^2 \theta d\psi) \right)^2 + \right. \\ \left. c_2^2 (b \sin^2 \theta d\phi + a \cos^2 \theta d\psi)^2 + c_3^2 (b \sin^2 \theta d\phi + a \cos^2 \theta d\psi)^2 \right]$$

Doing the same for (s_1, s_3) ,

$$O(0) : \frac{2m}{\Sigma} \left[\frac{1}{H_2} \frac{1}{s_2^2} \left(c_2 dt - \frac{c_1 c_2 c_3}{c_2} (a \sin^2 \theta d\phi + b \cos^2 \theta d\psi) \right)^2 + \right. \\ \left. c_1^2 (b \sin^2 \theta d\phi + a \cos^2 \theta d\psi)^2 + c_3^2 (b \sin^2 \theta d\phi + a \cos^2 \theta d\psi)^2 \right]$$

Doing the same for (s_1, s_2) ,

$$O(0) : \frac{2m}{\Sigma} \left[\frac{1}{H_3} \frac{1}{s_3^2} \left(c_3 dt - \frac{c_1 c_2 c_3}{c_3} (a \sin^2 \theta d\phi + b \cos^2 \theta d\psi) \right)^2 + \right. \\ \left. c_1^2 (b \sin^2 \theta d\phi + a \cos^2 \theta d\psi)^2 + c_2^2 (b \sin^2 \theta d\phi + a \cos^2 \theta d\psi)^2 \right]$$

Example. (Four charge AdS₄ solution) We first present the explicit form of the solution and the gauge fields,

$$ds^2 = \frac{W}{\Sigma} \left[- \frac{\Sigma(r^2 + a^2 \cos^2 \theta - 2mr)}{W^2} \left(dt + \frac{2ma \sin^2 \theta (rc_1 c_2 c_3 c_4 - (r - 2m)s_1 s_2 s_3 s_4)}{r^2 + a^2 \cos^2 \theta - 2mr} d\phi \right)^2 \right. \\ \left. + \Sigma \left(\frac{dr^2}{r^2 + a^2 - 2mr} + d\theta^2 + \frac{r^2 + a^2 - 2mr}{r^2 + a^2 \cos^2 \theta - 2mr} \sin^2 \theta d\phi^2 \right) \right]$$

Meanwhile, the gauge fields are given as

$$A_i = \frac{2m}{aW^2} \left[\left(\frac{r_1 r_2 r_3 r_4}{r_i} + ru^2 \right) [c_i s_i a dt - (a^2 - u^2) \left(\frac{c_1 c_2 c_3 c_4}{c_i} s_i - \frac{s_1 s_2 s_3 s_4}{s_i} c_i \right) d\phi] \right. \\ \left. + 2mu^2 [e_i a dt - (a^2 - u^2) \frac{s_1 s_2 s_3 s_4}{s_i} c_i d\phi] \right]$$

where

$$e_i = \frac{c_1 c_2 c_3 c_4 s_1 s_2 s_3 s_4}{c_i s_i} (c_i^2 + s_i^2) - c_i s_i \left(\sum_{\substack{j < k \\ j, k \neq i}} s_j^2 s_k^2 + \frac{2s_1^2 s_2^2 s_3^2 s_4^2}{s_i^2} \right)$$

and

$$H_i = 1 + \frac{2mr s_i^2}{\Sigma} \quad c_i = \sqrt{1 + s_i^2} \quad r_i = r + 2m s_i^2$$

$$W^2 = (r_1 r_2 + u^2)(r_3 r_4 + u^2) - 4mu^2(s_1 s_2 c_3 c_4 - c_1 c_2 s_3 s_4)^2$$

Performing a Taylor expansion of the terms inside the warp factor with respect to (s_2, s_3, s_4) we find (up to $O(s_2^4, s_3^4, s_4^2)$ terms and subtracting the pure AdS terms)

$$O(0) : - \frac{\Sigma(r^2 + a^2 \cos^2 \theta - 2mr)}{(r_1 r + u^2)(r^2 + u^2)} \left(dt + \frac{2mrc_1 a \sin^2 \theta}{r^2 + a^2 \cos^2 \theta - 2mr} d\phi \right)^2$$

$$+ \Sigma \left(\frac{dr^2}{r^2 + a^2 - 2mr} + d\theta^2 + \frac{r^2 + a^2 - 2mr}{r^2 + a^2 \cos^2 \theta - 2mr} \sin^2 \theta d\phi^2 \right)$$

Doing the same for (s_1, s_3, s_4) ,

$$O(0) : - \frac{\Sigma(r^2 + a^2 \cos^2 \theta - 2mr)}{(r_2 r + u^2)(r^2 + u^2)} \left(dt + \frac{2mrc_2 a \sin^2 \theta}{r^2 + a^2 \cos^2 \theta - 2mr} d\phi \right)^2$$

$$+ \Sigma \left(\frac{dr^2}{r^2 + a^2 - 2mr} + d\theta^2 + \frac{r^2 + a^2 - 2mr}{r^2 + a^2 \cos^2 \theta - 2mr} \sin^2 \theta d\phi^2 \right)$$

Doing the same for (s_1, s_2, s_4) ,

$$O(0) : - \frac{\Sigma(r^2 + a^2 \cos^2 \theta - 2mr)}{(r_3 r + u^2)(r^2 + u^2)} \left(dt + \frac{2mrc_3 a \sin^2 \theta}{r^2 + a^2 \cos^2 \theta - 2mr} d\phi \right)^2$$

$$+ \Sigma \left(\frac{dr^2}{r^2 + a^2 - 2mr} + d\theta^2 + \frac{r^2 + a^2 - 2mr}{r^2 + a^2 \cos^2 \theta - 2mr} \sin^2 \theta d\phi^2 \right)$$

Doing the same for (s_2, s_3, s_4) ,

$$O(0) : - \frac{\Sigma(r^2 + a^2 \cos^2 \theta - 2mr)}{(r_4 r + u^2)(r^2 + u^2)} \left(dt + \frac{2mrc_4 a \sin^2 \theta}{r^2 + a^2 \cos^2 \theta - 2mr} d\phi \right)^2$$

$$+ \Sigma \left(\frac{dr^2}{r^2 + a^2 - 2mr} + d\theta^2 + \frac{r^2 + a^2 - 2mr}{r^2 + a^2 \cos^2 \theta - 2mr} \sin^2 \theta d\phi^2 \right)$$

Simplifying the first expression we found and subtracting the pure AdS part, we find

$$\frac{2mr}{\Sigma H_1} (c_1 dt - a \sin^2 \theta d\phi)^2$$

UNGAUGED FOUR CHARGE ANSATZ

Using the knowledge from the coefficient determination process above and also educated guess work, I was able to arrive at the following form of the ungauged four charge ansatz.

$$ds^2 = \frac{W}{r^2 + a^2 \cos^2 \theta} \left[-dt^2 + (r^2 + a^2 \cos^2 \theta) \left(\frac{dr^2}{r^2 + a^2 - 2mr} + d\theta^2 \right) + (r^2 + a^2) \sin^2 \theta d\phi^2 + \frac{W^2}{2m} \left(\sum_{i=1}^4 F_i A_i^2 + \sum_{i=1}^4 (G_i - F_i) [A_i^{(\phi)}]^2 \right) \right]$$

where $A_i^{(\phi)}$ denotes the ϕ -part of the gauge field A_i and F_i and G_i each denote the following:

$$\begin{cases} F_i = \left(\frac{r_1 r_2 r_3 r_4}{r_i} + r a^2 \cos^2 \theta + 2 m a^2 \cos^2 \theta \frac{e_i}{c_i s_i} \right)^{-1} s_i^4 \left(\prod_{j \neq i} (s_i^2 - s_j^2)^{-1} \right) \\ G_i = \left(\frac{r_1 r_2 r_3 r_4}{r_i} + r a^2 \cos^2 \theta + 2 m a^2 \cos^2 \theta \frac{s_1 s_2 s_3 s_4 c_i^2}{c_1 c_2 c_3 c_4 s_i^2 - s_1 s_2 s_3 s_4 c_i^2} \right)^{-1} s_i^4 \left(\prod_{j \neq i} (s_i^2 - s_j^2)^{-1} \right) \end{cases}$$

GENERAL GAUGED FOUR CHARGE ANSATZ

The ungauged four charge ansatz above compels us to start constructing the gauged four charge ansatz we've been building towards. Due to the elegance of the Wu form, the pure anti-de Sitter part has a trivial gauged generalisation, namely

$$ds^2 = \frac{W}{r^2 + a^2 \cos^2 \theta} \left[- \frac{(1 + g^2 r^2)(1 - a^2 g^2 \cos^2 \theta)}{1 - a^2 g^2} dt^2 + (r^2 + a^2 \cos^2 \theta) \left(\frac{dr^2}{\Delta_r} + \frac{d\theta^2}{1 - a^2 g^2 \cos^2 \theta} \right) + \frac{r^2 + a^2}{1 - a^2 g^2} \sin^2 \theta d\phi^2 + \frac{W^2}{2m} \left(\sum_{i=1}^4 F_i A_i^2 + \sum_{i=1}^4 (G_i - F_i) [A_i^{(\phi)}]^2 \right) \right]$$

and the new gauge fields would be defined through the equality

$$\begin{aligned} \frac{W^2}{2m} A_i = & \left(\frac{r_1 r_2 r_3 r_4}{r_i} + 2 m a^2 \cos^2 \theta \frac{e_i}{c_i s_i} + r a^2 \cos^2 \theta \right) \\ & \times \left[K_1 c_i s_i dt - K_2 a \sin^2 \theta \left(\frac{c_1 c_2 c_3 c_4 s_i}{c_i} - \frac{s_1 s_2 s_3 s_4 c_i}{s_i} \right) d\phi \right] \\ & + K_3 2 m a^2 \cos^2 \theta \left(\frac{c_1 c_2 c_3 c_4}{c_i^2} e_i - \frac{s_1 s_2 s_3 s_4}{s_i^2} (e_i + c_i s_i) \right) a \sin^2 \theta d\phi \end{aligned}$$

Notice that we have a total of 5 undetermined elements, namely $(\Delta_r, K_1, K_2, K_3)$. We suggest the following methods for the determination process:

- (i) Proper truncation limits for the two independent charge case and the pairwise identification case

(ii) Educated guesswork using symmetry and the original Wu paper

We will try to employ these techniques in this exact order.

GAUGED ELECTRIC POTENTIALS

Definition. (Discrete inversion symmetry) The solution is expected to be invariant under the transformation

$$a \rightarrow \frac{a}{(ag)^2} \quad r \rightarrow \frac{r}{(ag)} \quad a \cos \theta \rightarrow \frac{a \cos \theta}{(ag)} \quad m \rightarrow \frac{m}{(ag)^3} \quad \phi \leftrightarrow gt \quad s_i \rightarrow (ag)s_i$$

We define the weight of some function $w(f)$ as the power of ag it obtains as it goes through the transformation.

Lemma. (Symmetrising W) We try to determine the gauged W through matching the weights of the term as they go through the inversion transformation denoted above. Consider the following function

$$W^2 = r_1 r_2 r_3 r_4 + u^4 + u^2 \left[2r^2 + 2mr(s_1^2 + s_2^2 + s_3^2 + s_4^2) + 8m^2 c_1 c_2 c_3 c_4 s_1 s_2 s_3 s_4 - 4m^2 (s_{123}^2 + s_{124}^2 + s_{134}^2 + s_{234}^2 + 2s_{1234}^2) \right]$$

we can make this function uniformly of weight $w(W^2) = -4$ by writing

$$W^2 = r_1 r_2 r_3 r_4 + u^4 + u^2 \left[2r^2 + 2mr(s_1^2 + s_2^2 + s_3^2 + s_4^2) + 8m^2 c_{1234} s_{1234} - 4m^2 s_{1234} \sqrt{(c_1^2 - 1)(c_2^2 - 1)(c_3^2 - 1)(c_4^2 - 1)} \left(\frac{1}{c_4^2 - 1} + \frac{1}{c_3^2 - 1} + \frac{1}{c_2^2 - 1} + \frac{1}{c_1^2 - 1} + 2 \right) \right]$$

If we additionally impose (naturally, as our metric has a factor $W/(r^2 + a^2 \cos^2 \theta)$) that $W^2 \rightarrow W^2/(ag)^4$, we need to multiply each c_i by $\tilde{c}_i$, giving

$$W^2 = r_1 r_2 r_3 r_4 + u^4 + u^2 \left[2r^2 + 2mr(s_1^2 + s_2^2 + s_3^2 + s_4^2) + 8m^2 \tilde{c}_{1234} c_{1234} s_{1234} - 4m^2 s_{1234} \left(\prod_{i=1}^4 \sqrt{\Xi_i c_i^2 - 1} \right) \left(\frac{1}{\tilde{c}_4^2 c_4^2 - 1} + \frac{1}{\tilde{c}_3^2 c_3^2 - 1} + \frac{1}{\tilde{c}_2^2 c_2^2 - 1} + \frac{1}{\tilde{c}_1^2 c_1^2 - 1} + 2 \right) \right]$$

The uniqueness of this invariant form must be thought of further.

Proposition. (Ansatz for symmetric A_i) We try to determine the gauged A by going

through a similar process denoted above. Consider the ungauged electric potential

$$A_1 = \frac{2m}{W^2} \left[(r_1 r_2 r_3 + r a^2 \cos^2 \theta) \underbrace{(c_1 s_1 dt - a \sin^2 \theta (c_2 c_3 c_4 s_1 - s_2 s_3 s_4 c_1) d\phi)}_{(I)} + 2ma^2 \cos^2 \theta \underbrace{(e_1 dt - a \sin^2 \theta s_2 s_3 s_4 c_1 d\phi)}_{(II)} \right]$$

Firstly, we must notice that a overall factor of $1/\Xi$ is obvious, given the need of a sign flip under inversion. In the process of employing inversion symmetry, we divide the gauge fields into two parts, (I) and (II). Gauging part (I) is relatively simple. We need to start by first noticing that the overall coefficients simply have a weight of 0, and that we expect the section to map onto itself perfectly up to a sign difference.

$$A_1^{(I)} = (c_1 s_1 \tilde{c}_2 \tilde{c}_3 \tilde{c}_4 - (ag)^2 \tilde{c}_1 s_2 s_3 s_4) \Delta_\theta dt - a \sin^2 \theta (\tilde{c}_1 c_2 c_3 c_4 s_1 - s_2 s_3 s_4 c_1) d\phi$$

Here, a problem is that any factor of $\tilde{c}_i$ can add to the last term, which needs further investigation. What about part (II)? This time, the overall factors scale by -2 and we are compelled to think that part (II) should scale by 2 . We conclude

$$A_1^{(II)} = e_1 \Delta_\theta dt - \left[(\tilde{c}_1^2 + (ags_1)^2) \tilde{c}_2 \tilde{c}_3 \tilde{c}_4 s_2 s_3 s_4 - (ag)^2 \tilde{c}_1 s_1 (s_2^2 s_3^2 + s_2^2 s_4^2 + s_3^2 s_4^2 + 2(ag)^2 s_2^2 s_3^2 s_4^2) \right] a \sin^2 \theta d\phi$$

for $e_1 = c_2 c_3 c_4 s_2 s_3 s_4 (c_1^2 + s_1^2) - c_1 s_2 (s_2^2 s_3^2 + s_2^2 s_4^2 + s_3^2 s_4^2 + 2s_2^2 s_3^2 s_4^2)$. Notice that again, we have the freedom to add $\tilde{c}_i$ terms to any term dependent of the factor (ag) . Momentarily ignoring the fact, generalising the two, we find

$$A_i^{(I)} = \left(c_i s_i \frac{\tilde{c}_1 \tilde{c}_2 \tilde{c}_3 \tilde{c}_4}{\tilde{c}_i} - (ag)^2 \tilde{c}_i \frac{s_1 s_2 s_3 s_4}{s_i} \right) \Delta_\theta dt - \left(\tilde{c}_i s_i \frac{c_1 c_2 c_3 c_4}{c_i} - c_i \frac{s_1 s_2 s_3 s_4}{s_i} \right) a \sin^2 \theta d\phi$$

and

$$A_i^{(II)} = e_i \Delta_\theta dt - \left[(\tilde{c}_i^2 + (ags_i)^2) \frac{\tilde{c}_1 \tilde{c}_2 \tilde{c}_3 \tilde{c}_4}{\tilde{c}_i} \frac{s_1 s_2 s_3 s_4}{s_i} - (ag)^2 \tilde{c}_i s_i \left(\sum_{\substack{j < k \\ j, k \neq i}} s_j^2 s_k^2 + 2(ag)^2 \frac{s_1^2 s_2^2 s_3^2 s_4^2}{s_i^2} \right) \right] a \sin^2 \theta d\phi$$

It is easy to verify that these expressions accurately reduce to the ungauged limit for the four charge case.

Remark. At this point, we've found a parity conforming ansatz for our electric potentials A_i . However, recall that our radial functions F_i and $G_i - F_i$ were also functions of charge which were derived from a particular linearisation process.

$$\frac{W^2}{2m} \left(\sum_{i=1}^4 F_i A_i^2 + \sum_{i=1}^4 (G_i - F_i) [A_i^{(\phi)}]^2 \right)$$

In order to gauge these functions, we apply to logic to the gauged electric potentials. An ultimate test that this sector of the ansatz must pass would be the fact that it would be invariant under parity. Including this certain parity test, we have the following limits that the we want to use to verify and edit our current ansatz and gauge potentials.

- (i) Correct independent charge limit
- (ii) Correct two pairwise equal charge limit
- (iii) Symmetric under parity

Well if our current form or perhaps a bit of an improvement yields these results (especially the last one) correctly, it would be really nice!

Proposition. (Two independent charge limit) We see that under the two independent charge limit, the gauged electric potential reduces to

$$A_1 = \frac{2m}{W^2} \left[(r_1 r_2 r_3 + r a^2 \cos^2 \theta) A_1^{(I)} + 2 m a^2 \cos^2 \theta A_1^{(II)} \right]$$
